

**A STUDY OF RADIO RECOMBINATION LINES
FROM THE GALACTIC PLANE
AT 325 MHz**

Thesis submitted to the
BANGALORE UNIVERSITY
for the degree of
DOCTOR OF PHILOSOPHY

By
K. R. ANANTHARAMAIAH

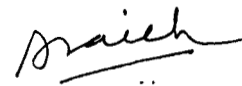

RAMAN RESEARCH INSTITUTE

Bangalore-560 080, India

JULY 1984

DECLARATION

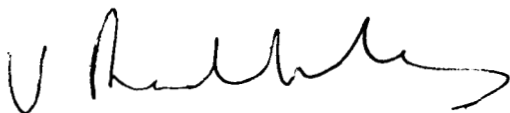

I declare that the work presented in this thesis has been conducted by me in the Raman Research Institute, Bangalore, India. No part of this work has been submitted for the award of any other degree, diploma, associateship, fellowship or any similar title.

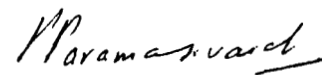

(K.R. ANANTHARAMAIAH)

CERTIFIED

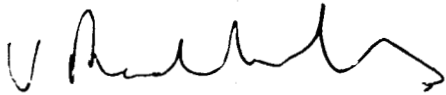

(V. RADHAKRISHNAN, GUIDE)

(P. PARAMASIVIAH, GUIDE)

CERTIFICATE

We certify that this thesis has been composed by K.R. Anantharamaiah based on investigations carried out by him at the Raman Research Institute, Bangalore, India, under our supervision. The subject matter of this thesis has not previously formed the basis of the award of any degree, diploma, associateship, fellowship or other similar title.

A STUDY OF RADIO RECOMBINATION LINES
FROM THE GALACTIC PLANE AT 325MHz

SYNOPSIS

Studies of radio recombination lines are useful in understanding the distribution, kinematics and thermodynamic properties of the ionized gas in the galaxy. Recombination lines mainly of hydrogen and helium, and to some extent of carbon have earlier been observed over a wide range of frequencies from 86GHz to 26MHz corresponding to the transitions from principal quantum number levels $n=42$ and $n=630$ respectively. From many such studies it has now become clear that there is a whole hierarchy of ionized regions with different densities, temperatures and sizes distributed in different ways in the galaxy.

In a heterogeneous medium, recombination line observations at different frequencies sample different components of the ionized gas. In particular, recombination line emission at low frequencies ($<1\text{GHz}$) is expected to be **dominated** by low density ionized regions. Those at high frequencies originate in high density ionized gas typical of **HII** regions prominent in most radio continuum surveys. This is because low frequency line emission from high density gas is suppressed due to opacity and pressure broadening, while from low density regions it is enhanced by stimulated emission in the presence of strong background continuum sources or even the **nonthermal** galactic background. Frequencies below 500MHz are best suited to study conditions in cold partially ionized gas and in large low density ionized regions. For the latter, beam dilution due to the poorer angular resolutions available at low frequencies is also not important.

Most existing large scale recombination line surveys of the galaxy have been carried out at frequencies higher than 1 GHz. Below 500 MHz, **there** are only a handful of observations made towards a few selected sources in the galactic plane. Weak recombination lines have been detected at centimetric wavelengths

at several positions along the galactic ridge. These lines, which are known as 'galactic ridge recombination lines', were initially thought to be coming from cold partially ionized clouds in the interstellar medium but are now believed to be due to low density hot gas, presumably weak **HII** regions. However, there are no comparable observations at frequencies below **500MHz** to help understand these galactic ridge **recombination** lines.

In this thesis we present observations and interpretation of recombination lines from the galactic plane at a frequency of 325 MHz corresponding to a transition from principal quantum number $n=273$ to $n=272$. This study is based on observations made towards 53 directions in the galactic plane using the Ooty radio telescope which operates at a nominal centre frequency of 326.5 MHz.

The present observations made over a period of 3 years constitute the first major spectral line study carried out using the Ooty telescope. In the first part of this thesis we describe in detail the **equipment, observing** procedure, the precautions necessitated by the use of such a phased array telescope for line studies and the data reduction methods.

The 53 directions in the galactic plane chosen for this study consist of 34 directions corresponding to well known **HII** regions, 12 corresponding to supernova remnants and 6 directions of continuum minimum which we call as 'blank regions'. The majority of the observed directions lie in the first quadrant of the galaxy but a few sources were selected in the anticentre direction where the nonthermal galactic background is considerably weaker. Observations towards the **HII** regions were used to study the properties of low density ionized gas associated with them, and those towards **SNRs** and blank regions to study any low density ionized gas along the line of sight.

In this thesis we present the results of these observations. Hydrogen recombination lines ($H272\alpha$) were detected in 47 of the 53 directions observed and possibly carbon recombination lines

(C272 α) in 12 of these directions. The intensity of the recombination lines detected in this study were found to correlate well with the total continuum intensity in all directions observed irrespective of whether the direction corresponds to that of an **HII** region, an SNR or a blank region. As the continuum radiation at this frequency is mainly nonthermal in origin, the correlation observed indicates that most of the lines arise due to stimulated emission by the background radiation.

We show in this thesis that most of recombination lines observed here are not produced within the **HII** regions which are prominent continuum sources in the **galactic** plane; they are shown to be coming from low density outer envelopes of the **HII** regions. Applying the theory of formation of recombination lines to the line **parameters** observed here and in other observations at different frequencies available in the literature, we have deduced the density, temperature and sizes of **the** ionized regions in the direction of blank regions and SNRs. For the lines seen **towards HII regions we have used** the observed velocity agreement with higher frequency lines and invoked geometrical considerations to deduce the properties of the outer low density envelopes. We find that the gas responsible for the lines has an electron density of 1-10 cm^{-3} , an electron temperature of 3000-8000K and that it extends over 50-300 pc along the line of sight.

We have compared the observed velocities of these low density regions with those of **HII** regions observed in high frequency recombination line surveys and find that there is generally a very good agreement suggesting a physical association in most cases. Further, we have used the longitude-velocity diagram of the observed lines together with a model of the galactic rotation to deduce the distribution of these low density regions in the galactic disk. A comparison is then made of this distribution with those of other components of the interstellar medium like the neutral hydrogen, **HII** regions, giant molecular clouds, and SNRs. We find that this gas is not distributed like

the neutral hydrogen thereby ruling out the possibility that the lines arise in partially ionized cold HI gas. Its distribution shows a peak **between** 4 kpc and 8 kpc from the galactic centre and is similar to those of **HII** regions, giant molecular clouds and **SNRs**.

Based on the result of this study we suggest in this thesis that most, and probably all, of the galactic ridge recombination lines come from extended outer low density envelopes of conventional **HII** regions which are prominent in the radio continuum maps of the galactic plane. We show that conventional **HII** regions are so large in number in the galactic longitude range $1 \leq 40^\circ$ that given the kind of envelope sizes derived from the present observations, their outer regions will intersect practically every line of sight within this range thereby giving rise to the observed ridge lines. The present observations are shown to have the unique advantage that they are practically insensitive to line emission from conventional **HII** regions and that they have detected only that gas which is responsible for the galactic ridge recombination lines.

We have also appended to the thesis the results of two other investigations carried out during the course of the above study. Although not central to the main theme of the thesis they relate to an understanding of the composition and state of the interstellar gas, probed by the recombination line investigations. The first of these is the most sensitive yet attempt to observe the ground state hyperfine transition of interstellar deuterium. No positive detection was made but a **limit** to the atomic deuterium to hydrogen ratio was obtained consistent with ultraviolet observations from satellites in the directions of bright nearby stars.

The second investigation concerns the velocity distribution of interstellar hydrogen, in particular the non-circular motions which appear as peculiar velocities. The method involved a comparison of the velocities obtained in a given direction from recombination line and neutral hydrogen (21cm) observations. The

results provided strong support for a picture in which the interstellar hydrogen clouds could be categorized into two populations with very different velocity dispersions.

ACKNOWLEDGEMENTS

Any observational project which involves building, testing and installing of new instruments and, finally getting them to do what is intended, necessarily involves many people at different stages. I thank all my colleagues at the Raman Research Institute, who were involved in this project and the staff of the Radio Astronomy Centre, Ooty, who provided excellent support during the observations.

I thank my advisers V. Radhakrishnan and P. Paramasivaiah for help in all the matters related to this thesis. I take this opportunity to express my gratitude to V. Radhakrishnan for, among other things, teaching me the ways and means of radio observations and scientific research.

I thank Arora, Chandrakumar, Ravindra and Uday Shankar who were involved in building and testing of several of the instruments and Nataraja who helped me in developing some of the software. I have benefited a lot from discussions with them and also with N. V. G. Sarma. I am grateful to Rajaram Nityananda for his good suggestions and critical comments at all stages of this thesis.

I thank G. Swarup for his keen interest in this project and M. N. Joshi for teaching me the methods of using the Ooty Radio Telescope. The long sessions of observation at Ooty would not have been possible without the help of the telescope operators and the dedicated maintenance staff at the Radio Astronomy Centre. I thank them all for their active support and would particularly mention Rajagopal, Manoharan, Babu Mallargee, Ramesh, Baby Jaison, Selvanayagam, Venkataraman, Menon, Nagarathnam, Bhaskaran, Subramanian and Ravi. I thank the TIFR centre, Bangalore for providing me the use of their computing facility.

I thank Dipankar Bhattacharya for many discussions I had

with him and my other colleagues in the Astrophysics group for not only providing a cheerful atmosphere, but also for being keenly interested in the progress of this work.

Throughout the course of this work I, like all others at RRI, have received very good help from the Library staff in all matters related to scientific literature and reprography. I thank them all and particularly mention Ratnakar and Hanumappa for their care and efficiency in making copies of this thesis.

I thank Lakshmi for cheerfully typing several sections of this thesis and Somu, Raju, Namburaman and Ramachandra Rao, for their neat jobs of tracings and photography. I am indebted to Raman for providing me food at odd hours I was keeping during several stages of this work.

I suppose a thesis never gets written without several people asking about it all the time. I thank all those who induced me into finally sitting down to it and in particular I am grateful to my friends Jyotsna and Ganesh who, apart from asking me about it, helped in several ways to complete it.

CONTENTS

Synopsis

Aknowledgements

Chapter 1. INTRODUCTION

1. 1	RADIO SPECTRAL LINES	1-1
1. 2	RADIO RECOMBINATION LINES	1-2
1. 3	HII REGIONS	1-3
1. 4	GALACTIC RIDGE RECOMBINATION LINES	1-4
1. 5	SCOPE OF THE PRESENT WORK	1-5

Chapter 2. PHYSICS OF RADIO RECOMBINATION LINES

2.1	PHYSICAL PROESSES IN HII REGIONS	2-1
2.2	OPTICAL RADIATION FROM HII REGIONS	2-4
2. 3	RADIO CONTINUUM EMISSION	2-6
2. 3.1	Radiation transfer	2-6
2. 3.2	The continuum optical depth	2-8
2. 3.3	The continuum spectrum	2-9
2. 3.4	Properties of HII regions from continuum observations	2-11
2. 4	RADIO RECOMBINATION LINES	2-12
2. 4.1	Line frequencies	2-13
2. 4.2	Observable quantities	2-13
2. 4.3	Line radiation transfer	2-18
2. 4.4	LTE line optical depth	2-20
2. 4.5	The line profile function	2-22
2. 4.6	Intensity and width of the lines in LTE	2-24
2. 5	NON-LTE EFFECTS IN THE FORMATION OF RECOMBINATION LINES	2-28
2. 5.1	The b_n calculation	2-30
2. 5.2	Non-LTE optical depth	2-33
2. 5.3	Stimulated emission	2-34
2. 5.4	Non-LTE line intensities	2-35
2. 5.4.1	Isolated HII region	2-37
2. 5.4.2	A cloud in front of a strong background source	2-38
2. 6	THEORETICAL LINE INTENSITIES FROM MODEL PLASMA CLOUDS	2-39

Chapter 3. THE TELESCOPE, RECEIVER SYSTEM AND THE SPECTRAL LINE BACK-END

3.1	THE ANTENNA	3-1
3.2	THE RECEIVER SYSTEM	3-2
3.3	SENSITIVITY OF THE ORT	3-5
3.3.1	The system temperature	3-6
3.3.2	Sensitivity measurement using the correlation beam	3-6
3.3.3	Sensitivity measurement using total power beam	3-8
3.3.4	Efficiency of the ORT system	3-10
3.3.5	ORT system noise in units of apparent brightness temperature and apparent flux density	3-12
3.3.6	Effective area of the ORT	3-14
3.4	SPECTRAL LINE RECEIVERS	3-15
3.5	AUTOCORRELATION SPECTROMETER	3-17
3.5.1	The method	3-17
3.5.2	Advantages of the autocorrelation method	3-21
3.6	A ONE-BIT AUTOCORRELATION SPECTROMETER FOR THE ORT	
3.6.1	PRINCIPLE OF THE 1-BIT METHOD	3-22
3.6.2	FRONT END ANALOG SYSTEM	3-25
3.6.3	THE FIRST LOCAL OSCILLATOR	3-26
3.6.4	THE DIGITAL CORRELATOR	3-28
3.6.5	THE DATA ACQUISITION SOFTWARE	3-31
3.6.6	THE PERFORMANCE OF THE AUTO- CORRELATION SPECTROMETER	3-32
CHAPTER 4. <u>OBSERVING PROCEDURE AND DATA REDUCTION METHODS</u>		
4.1	THE NATURE OF SPECTRAL LINES	4-1
4.2	THE SWITCHING SCHEME	4-2
4.3	THE BASELINE CURVATURE	4-3
4.4	CALIBRATION OF THE SPECTRUM	4-8
4.5	THE OBSERVING PROCEDURE	4-11
4.6	DATA REDUCTION	4-12
4.6.1	Software for data reduction	4-16
4.7	THE INTERFERENCE PROBLEM	4-18
Chapter 5. <u>SOURCE POSITIONS, OBSERVATIONS AND RESULTS</u>		
5.1	AIM OF THE OBSERVATIONS	5-1
5.2	OBSERVING FREQUENCY	5-3
5.3	SOURCE POSITIONS	5-4
5.4	OBSERVATIONS AND DATA REDUCTION	5-6

5.5	RESULTS OF THE OBSERVATIONS	
5.6	COMPARISON WITH OTHER LOW FREQUENCY OBSERVATIONS	5-12
5.7	BROAD IMPLICATIONS OF THE RESULTS	5-12
5.7.1	Line intensities	5-13
5.7.2	Stimulated emission	5-14
5.7.3	The line velocities	5-14
5.7.4	The $l-v$ diagram	5-15

Chapter 6. INTERPRETATION OF THE OBSERVED LINES

6.1	GENERAL CONSIDERATIONS	6-1
6.2	UPPER LIMITS ON THE ELECTRON DENSITY FROM THE OBSERVED LINE WIDTHS	6-4
6.3	ANALYSIS OF LINES OBSERVED TOWARDS BLANK REGIONS	6-4
6.3.1	Calculation of the departure coefficients	6-6
6.3.2	Intensity of 166α and 272α lines as a function of N_e and T_e	6-7
6.3.3	A model for interpretation of the observed line intensities	6-10
6.3.4	Electron density of the gas	6-11
6.3.5	Electron temperature and emission measure	6-14
6.4	IONIZED GAS TOWARDS SNRs	6-18
6.4.1	Electron density of the gas	6-20
6.4.2	Electron temperature and emission measure	6-21
6.5	DISCUSSION OF THE DERIVED PARAMETERS TOWARDS BLANK REGIONS AND SNRs	6-23
6.6	LINES OBSERVED TOWARDS HII REGIONS	6-26
6.6.1	General considerations	6-26
6.6.2	Electron temperature of the low density envelopes	6-29
6.6.3	Electron density and emission measure	6-30
6.6.4	Discussion of the derived parameters	6-33

Chapter 7. DISTRIBUTION OF THE LOW DENSITY GAS AND THE ORIGIN OF THE GALACTIC RIDGE RECOMBINATION LINES

7.1	THE LONGITUDE-VELOCITY DIAGRAM	7-1
7.2	DISTRIBUTION AS A FUNCTION OF GALACTO-CENTRIC DISTANCE	7-3

7.3 ORIGIN OF THE GALACTIC RIDGE
RECOMBINATION LINES

7-6
