## ACKNOWLEDGMENTS

We are obliged to our professor and Head of the department of electronics engineering Prof. B.K Anathaswamy for the encouragement and help he has given us.

We are grateful to the Director, Raman research Institute, and Dr. KR Anantharamaiah for having given us an opportunity to undertake our project work in this reputed institute.

We are highly indebted to our guide Mr. A. Santhosh Kumar, who has motivated and guided us and has been a source of inspiration throughout our project. work.

We wish to express gratitude to Dr. T.S Rukmini, department of Electronics, R V College of Engineering, for her guidance and support during the course of our project.

We would like to thank Mr. H.N. Nagaraj for his invaluable help in the design of PCB's.

We would like to express our gratitude to field staff in Gauribidanur for cooperating with us during our stay there

Last but not the least we wish to acknowledge the co-operation provided to us by all the staff members of the Electronics Lab and GMRT lab during the course of our project.

## PROJECT SYNOPSIS

## Introduction:

We are involved in designing and implementing a programmable High speed Multi Channel Data Acquistion cum Signal Processing System . The Buffered Data Router is going to the front end of the Fast Fourier Transform card (FFT) which forms the kernel of a digital spectrometer.

The FFT card was designed at RRI. At the heart of the FFT card lies a Fast Fourier Transform Processor the PDSP16150 from PLESSEY SEMICONDUCTORS. This digital spectrometer (including our BDR) will be assimilated into the Gauribidanur radio telescope, and will be used to study carbon radio recombination lines.

## Functional explanation:

The block diagram shows the overall Multi-Channel Digital Spectrometer hardware. The BDR is at the top of the hiearchy as far as data flow is concerned. The signals in analog domain are digitized and stored in memeory banks in BDR module itself. It is then furnished to the FFT module in contigious blocks.

The FFT module consists of the FFT chip which accepts data on two 16-bit input channels either as real or imaginary parts of a complex sequence or as two independent sequences. This chip then compiles the fast fourier transform of the input data at very high speed. The output is also in the form of 16 -bit integers.

This output is fed to an integrator, where the fourier samples, are integrated in order to extract the signal buried in noise. The pipelined adders required for integration are incorporated in high density EPLDs called FLEX devices.

A PC/AT based interface has been developed for high speed acquistion of data and then transfered directly on the hard disk, at speeds of a few Mbytes per second. This interface is designed to follow Extended Industry Standard Architecture (EISA) bus standards, which allows 32-bit transfers.

## Design of BDR:

The system is to be designed in such a way that it can acquire signal both in the time domain and in the frequency domain. To accomplish this, we intend to design the system around high speed ADCs, Multiplexers etc.

The design of the high speed BDR is still under scrutiny for the following reasons. We have two design philophies in mind, they are:
(a) To use only a single ultra high speed ADC with a analog multiplexer preceeding it.
(b) To use eight medium speed low cost ADCs

Is it feasible to use a single ultra high speed ADC operating at several megacycles per second with all the associated circuitry to compensate high
frequency errors or use eight ADCsfor the eight channels, operating at several kilocycles per second?

It is a problem of optimization of cost, performance and circuit simplicity.

Our BDR is programmable, in the sense that, the user can opt the number of channels (1to 8 ) and select the number of points for the FFT computation. The various modes of operation and the data rate can be 16 point complex at 24 Msamples/sec or 2*1024 point complex at 12Msamples/sec and so on.

We have to design the base band filters as depicted and a EISA interface for FFT card.

The BDR is going to have as a wide range of applications. Due to its programmable flexibility it can be used in a multitude of situations where the number of channels required vary. With just the EISA interface (excluding FFT card) the system can also perform as a high speed DAS. It can also be used as a general lab spectrum analyser. The design of the BDR is such that, in future when ultra high speed ADCs are available at low costs they can be swapped with the existing ones with rest of the circuitry unchanged.

## CHAPTER DNE PROJECT OVERVIEW

# B. E. (E \& C) Final Year Project 1994-95 Bangalore University 

### 1.1 INTRODUCTION.

Fourier Transform(FT) is fundamental tool of spectrum analysis used in several applications, both commercial and scientific Among its applications in Radio Astronomy, there is an ever-growing need for faster computation of FT over long sequences of data samples. Conventionally, this is realized with highly optimized, "fast" fourier transform algorithms written on high speed, general purpose computer system. In such a case, the cost to computation ratio for a general computer proves too very uneconomical. In several cases, it may be required to obtain spectra of signals in real-time, before recording. However there are many applications demanding a throughput rate that cannot be afforded by these computers and quite often, one needs a dedicated FT processor.

In real time applications, these devices may be used as embedded processors in the target circuits and can as well be interfaced suitably to work as "accelerators" for general purpose computers. Engineers at RRI have developed a flexible Digital Spectrometer Card(DSC) to function for both of these purposes.

The genesis of this design is a part of an ongoing Pulsar instrumentation work. Apart from observation of pulsars, the system can be used in a variety of astronomical applications like the Radio Recombinational lines studies, Electron Proton Annihilation studies, or as a general purpose Spectrometer which can perform long stretches of integrations

## B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University

### 1.2 MULTI - CHANNEL SPECTROMETER

At the heart of the SPECTROMETER is a DSP chip PDSP 16510. This is a dedicated FFT chip. This chip accepts data on two 16-bit input channels, either as the real and imaginary parts of a complex sequence, or as two independent real sequences. It can perform FFT over different lengths of data sequence, for example- $16,64,256 \& 1024$ points at the maximum rate of 12 M samples $/ \mathrm{sec}$. This output can be either acquired by a PC/AT with EISA BUS interface or can be integrated in the buffers of the DSC. The integration buffers are implemented by using FIFOs as the associated control logic will be bare minimum. The user can integrate the data up to 216 times in these buffers. When integrated, data can be written on to the hard disk. At the same time the integrated fourier transformed output will be written into the other FIFO and this process repeats.

The DSC does not include the necessary interface circuitry for interfacing the signats from the Real world domain to the Digital Domain. Being single channel spectrometer, it offers limited resolution. In order to develop a completely independent, multi-channel Digital Spectrometer, we have designed a programmable 8-channel Digitizer card and a Buffered Data Router(BDR). The over all block diagram of the system is shown in fig(1.I)

The programmable 8 channel Digitizer Card has a bank of 8 sample and hold circuits at the front end, for sampling the analog signals. It is followed by 8 xl analog multiplexer whose

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

output is fed to a 10 -bit ADC. This ADC is of FLASH type which can work at a maximum speed of $18 \mathrm{Msamples} / \mathrm{sec}$ and has a novel pipelined architecture. Due to its piplined architecture, after 4 clock cycles the digitized data flows out continuously. The start of conversion and end of conversion pulses are not necessary to digitize each sample, thus simplifying the control circuitry. The digitized data is then fed to the Buffered Data Router [BDR]

The BDR is equipped with a double buffer of SRAM memory chips and the necessary control logic. Input data is first written into BUFFER-A at the rate programmed by the user depending upon the input bandwidth. As soon as the programmed number of points per channel have been written, the address counter sends a buffer full signal to the MUX circuits. At this point the MUX swaps the buffers. The input data is now written into BUFFER-B while BUFFER-A will be read by host CPU or the DSC. The buffers are swapped again when BUFFER-B sends its buffer full signal to the MUX circuits, and this process repeats.

The ALTERA programmable logic development system was used to integrate various logic circuits into MAX-7000 and MAX-5000 family EPLDs. In fact we have used EPM7128LC84 (84-pin EPLD), which appertains to the MAX-7000 family while the other is EPM5016 (20-pin EPLD) of MAX-5000 family. These chips provide a comprehensive costeffective solution for designs, intensive in combinatorial logic.

## CHAPTERTWO

## DESIGN PHILOSOPHY

# B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University 

### 2.1 THE PROBLEM.

The crux of the problem lies in radio observations of low frequency Carbon Radio Recombination Lines (CRRLs) by making use of the Multi Channel Spectrometer. By "Lines" we ascribe to radiation at unique wavelengths. Every element has a unique emission spectrum - finger prints of elements. These lines are caused for the following reason. When an electron is excited by supplement of energy either thermal or non-thermal, the electrons move to an higher energy level (orbit). This state is quasi-stable state, hence it falls back to its previous stable state, i.e. lower energy level. In doing so the difference in energy is radiated as electromagnetic radiation. Since energy levels are quantized, the emitted energy is of definite wavelength

At the Gauribidanur Radio Telescope (GEETEE) [ please refer to Appendix-A.] the recombination lines can be observed at decametric wavelengths. The operating frequency of the GEETEE is $34.5 \mathbf{M H z}$, with a good usable bandwidth of $2 \mathbf{M H z}$. The CRRLs at these frequencies correspond to high principal quantum numbers around $574 \alpha$, with typical line widths of the order of 1 kHz . Within the observational bandwidth of GEETEE 12 of these CRRLs can be observed.[please refer to Appendix-B]. In order to observe these lines a

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

resolution of approximately 250 Hz is an essential condition. Hence it was conceived to build a stable Spectrometer, which could be used for the above said observations.

The DSC could not be used in its present form of single channel spectrometer, because of the poor resolution that could be obtained, which is elucidated in the following discussion.

The resolution of the Spectrometer is defined as:

## Resolution $=\mathbf{B W} / \mathbf{N} \mathbf{H z}$.

where BW is the Bandwidth and N is the number of points of FFT performed.

If we determine the resolution of the Spectrometer for 2 MHz bandwidth with 1024 points FFT it turns out to be

$$
\text { Resolution }=2 \mathrm{MHz} / 1024=1953.12500 \mathrm{~Hz}
$$

The resolution obtained is clearly inadequate for useful observations. In order to improve the resolution, we have hit upon the novel idea of splitting the 2 MHz bandwidth into 8 separate bands each of bandwidth 250 kHz and then performing a 1024 point FFT on each of them. This will improve the Resolution, by a factor of 8 and the resolution would now be Resolution $=250 \mathrm{kHz} / 1024=244.140625 \mathrm{~Hz}$
which could be used conveniently for the observations.

# B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University 

### 2.2 DESIGN PRINCIPLE OF DIGITIZER CARD.

The design dogma is now dictated by the reductio ad absurdum in the previous section. It is now clear that the number of input channels for $B D R$ is 8 . There are two design philosophies which can be implemented.

They are:
(a) To use a single high speed $A D C$ with a analog multiplxer.
(b) To use eight medium speed ADC s with a digital multiplxer.

The block diagram of the two designs are shown in fig(2.1). Comparing the two design philosophies, we will come to know that design (a) is cost effective and simple in terms of circuitry. The reasons are obvious, when one looks at the two designs. The first point we notice is that we need 8 ADCs for design (b) while only one ADC is sufficient for design (a). Since the ADCs are of 8-bit resolution we need a 8-bit 8:1 Digital Multiplexer for design (b). The Digital Multiplexer may not be available or may be too expensive. All these bottle necks are not encountered in design (a).

# B. E. (E \& C) Final Year Project 1994-95 Bangalore University 

### 2.3 DESIGN PRINCIPLE OF BUFFERED DATA ROUTER.

The BDR furnishes digitized data to the DSC card. It should take heed of supplying data in proper format and at required throughput rates so that both of them work in synchronism

When we give a "Sample" command to the $\mathrm{S} / \mathrm{H}$ circuit we are actually sampling 8 input analog signals appearing at 8 input channels. After digitizing we obtain a serial output of 8 data points, each of which corresponds to 8 channels in sequential order. It is quite evident that we cannot send these data words directly to DSC, becáuse individual data points do not have any correlation with each other as they are from different channels. There is one way out of this bottle neck, that is by storing the data temporarily on some storage device and then throughputting the data in contiguous blocks to the PDSP chip. Therefore we are making use of a memory (SRAM) as temporary storage

After 1024 data points from each channel has been written, it is read out of the memory in the fashion the PDSP desires. Subsequently we will be storing a maximum of $8 * 1024=$ 8192 data points. Inevitably we need a 8 K RAM chip to accommodate this data.

Continuum supply of data necessitates read and write simultaneously Since this is not possible on a RAM chip, we are left with a choice of using two 8 K RAM chips(of course, we

Dept. of E \& C Engineering, R.V.C.E. Bangalore

## B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University

could use Dual-Port RAM, but the control circuitry would be involving and complex) hence we restrain ourselves to a simple design involving two RAMs. We apportion 1 K in both of the 8 K RAM chips for each channel. Individual data points are written in their respective 1 K blocks. After 8192 samples and digitization we are left with one of the RAM chips full of data where in, each 1 K block of memory corresponds to one particular channel. Now we can read out of RAM chip and furnish this data to DSP Simultaneously we can continue to write fresh data into the second RAM chip. Under this circumstance the PDSP chip sees a continuous stream of data from BDR even though the acquisition is by fits and starts.

## CHAPTER THREE HARDWARE

## IMPLEMENT ATION

B. E. (E \& C) Final Year Project 1994-95

Bangalore University

### 3.1 DIGITIZER CARD IMPLEMENTATION

With the design of digitizer card finalized, it can be seen that it will require these basic components:

## - Sample and Hold circuits

- Analog Multiplexer
- Analog to Digital Converter

## Sample and Hold circuit:

The signals from all the 8 channels are sampled at the same instant of time. The $\mathrm{S} / \mathrm{H}$ circuits will be holding the same analog value till the next sample pulse is applied. With an input frequency band of 250 kHz , the Nyquist sampling frequency will be 500 kHz . So the time interval between two samples is $2 \mu$ sers. In this time period the ADC will have to digitize all 8 channel outputs starting from the first channel through the last channel in sequential order. Hence there will be $0.25 \mu$ seconds for each channel to be digitized. The S/H on the 8 th channel will therefore, have to hold its output for $1.75 \mu \mathrm{~seconds}$. We have chosen $A D 9100$ for sampling the analog signals, which has a typical droop rate of $1 \mathrm{mV} / \mu \mathrm{s}$. The droop in output voltage of the last $\mathrm{S} / \mathrm{H}$ is 1.75 mV . The resolution of the ADC used ( AD 773 ) is 0.97 mV . So a change of 1.75 mV at the $\mathrm{S} / \mathrm{H}$ output will lead to an approximate change of 2 bits in the digitized value of the ADC output. This

PCB Layout of S/H Circuit
Fig 3.1

# B. E. (E \& C) Final Year Project 1994-95 

## Bangalore University

kind of accuracy is acceptable for all practical purposes. The schematic and the PCB layout of the $\mathrm{S} / \mathrm{H}$ circuit is as shown in the fig (3.1a \& b). Further details of the S/H AD9100 can be found in Appendix D.

## Analog Multiplexer:

The Analog MUX will have to switch all the eight outputs of the $\mathrm{S} / \mathrm{H}$ circuits to the ADC for digitizing before the arrival of the next sample pulse. This gives it an interval of $0.25 \mu$ seconds to switch between two channels. This time should include all the delays involved in a MUX, like settling time and channel has a settling time of 70ns (typical), and channel switching time of 40 ns (typical). The AD 9300 is a $4: 1$ multiplexer. However, its output can be put into high impedance state. This will allow us to use two such MUXes in parallel, forming a $8: 1$ multiplexer. The schematic and PCB layout of the MUX are shown in $f i g(3.2 a \&$ b). Further details of the MUX can be found in Appendix $D$.

## Analog to Digital converter:

After the sample pulse is given to the $\mathrm{S} / \mathrm{H}$ circuits the Analog to Digital converter will have to digitize the outputs of all the 8 channels. So the ADC will have to operate at eight times the speed of the $\mathrm{S} / \mathrm{H}$ circuits. With a sampling frequency of 500 kHz given to the $\mathrm{S} / \mathrm{H}$ circuits, the ADC has to therefore, operate at 4 MHz , giving the ADC a conversion time of $0.25 \mu$ seconds. With this factor in view the ADC we selected was $A D 773$. It is a monolithic 10-bit, flash ADC, with a thrqughput rate of 18 MSPS ADC with a on board track and hold Dept. of $E \& C$ Engineering, R.V.C.E. Bangalore

FIG 3.20

PCB Layout of Analog MUX Circuit
Fig 3.2
B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

amplifier. AD773 is a pipe lined device. It has a delay of four clock pulses between an analog voltage applied at its input and the corresponding digitized data appearing at its output. It has an input range of 1 V (peak-to-peak). Since the resolution of a ADC is given by:

$$
\text { Resolution }=\text { input voltage swing } /\left(2^{n}\right) ;
$$

where n is the number of bits of ADC output.
This gives a resolution of ( $1 \mathrm{~V} /(1024)$

$$
\text { Resolution }=977.4 \mu V
$$

With a conversion time of $5.55 \times 10-08$, this ADC is ideally suited for specifications imposed by the Digitizer card. The schematic of the ADC and it's PCB layout is shown in fig (3.3a\&b). Further details regarding AD773 can be obtained in Appendix D.

FIG 3.3a

PCB Layout of ADC Circuit
Fig 3.3

## B. E. (E \& C) Final Year Project 1994-95 Bangalore University 3.2 BUFFERED DATA ROUTER

Spectrometric analysis of the signals received from the radio telescope is continuous process. This involves a continuous flow of data through the

## Buffered Data Router

 (fig(3.4)), to the FFT card. With 8 different channels involved, a rearrangement of digitized ADC output is needed. This is because the FFT chip requires the entire set of 1024 (or 512 or 256 ...) points of a single channel, given to it consecutively. But the ADC will be digitizing the signals of all the channels' one after another. So if at the $\mathrm{n}^{\text {th }}$ clock pulse, the digital output from ADC is from channel x (say), then at the $(\mathrm{n}+1)$ th clock pulse the digital output is from $(x+1)$ th channel. If the ADC output was to be given directly to the FFT card, two consecutive data outputs from the ADC will be from two entirely different channels as shown in fig (3.5). Processing of such a stream of data would lead to faulty results in the FFT output.To sort out this problem, rearrangement of the ADC output must be performed. This task involves temporary storage of digitized data on the $B D R$. RAMs are best suited for the job of temporary storage, when the required speed of operation and cost are taken into perspective. With the requirement of 1024 points FFT on all 8 channels, the total amount of data to be stored will be 8192 bytes, with 1 kB for each channel. Data from a channel will be written into its corresponding $l \mathrm{kB}$ block, after being digitized by the ADC . This stored data is then read in a stream of 1024 data points from the same channel.

To keep the data flowing ceaselessly, it must be read from and written into the RAMs simultaneously. But RAMs present a problem. At a given instant of time, they can perform

Fig 3.5
(1)

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

only one task, either reading or writing. Both these operations cannot be performed simultaneously. This predicament is preempted by using two separate memories. While one of them is storing data from the ADC , the other will be sending previously stored data down to the FFT card after the required rearrangement.

To perform this prestidigitation of writing and reading data simultaneously into the respective memories and then swapping the operation, the Buffered Data Router has been used.

The BDR consists of the following blocks:
(a) Sequencer Circuit
(b) Memory banks.

## 3.2-1 SEOUENCER CIRCUIT:

The sequencer circuit forms the quintessence of the Buffered Datt Router. It functions as an address generator for the two memories and also for controlling the read and write operations of static RAMs. The ability to program the number of points and channels involved in the FFT process, is one of the feature incorporated into the $\boldsymbol{B D R}$.. This means the user will stipulate the number of points and channels. This is a vital information for the sequencer circuitry.

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

The inputs to the sequencer circuit are as follows

> • number of points
> •number of channels
> •clock
> •enable signal

The stipulated number of channels and points are accepted from the user by means of a program written in C language. Using either an ISA or EISA interface card, this information is then fed to the $B D R$.. The sequencer circuit in the $\boldsymbol{B D R}$ accepts this data and stores it in the appropriate latches.

The block diagram of the sequencer circuit is as shown in fig(3.6). The sequencer circuit itself can be categorized as:
a) Address Generator and Multiplexer
b) Clock Controller

## ADDRESS GENERATOR:

The address generator is used for generating address sequence for read and operations performed on the two memories. In order to access all 8 k locations in the S-RAMs, a 13 bit address is required. This 13 bit address is generated by a 13 bit counter. With reading and writing address taking place simultaneously two address generators are required, namely, the read address generator and write address generator.

# B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University 

## (a) Write Address Generator:

As explained earlier, the memory is divided into eight 1 kB blocks and each 1 k block is for holding data from one channel. Two consecutive outputs of ADCs are from two different channels. They need to be stored into their respective 1 k blocks. Therefore at every clock pulse the write address generator has to increment itself by 1024 in order to point to the correct memory block. After storing data points from all $\mathrm{N}_{\mathrm{c}}$ channels it will have to switch to switch to first 1 k block and point to next free location in it. The sequence of write address generated is shown in fig(3.7)

To achieve this the write address generator is divided into 2 parts a 3 bit counter and a 10 bit counter. Both these counters are programmable. The number of points are programmed into the 10 bit counter and the number of channels are programmed into the 3 bit counter. The 3 bit counter is clocked by the master clock. At every clock pulse, it's incremented by one. The significance of this 3 bit counter, is that the 13 bit address is incremented by 1024 at every clock pulse. After being through with all the channels, this counter is reset. This reset pulse clocks the 10 bit counter and is incremented by one, thereby pointing to next location in the memory of the first 1 K block.

The write address generator circuit is shown in the overall circuit diagram. Refer to fig(3.9)

# B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University (b) Read Address Generator: 

The data stored in the memory has to read out sequentially into the FFT card. All data points stored in one 1 k block, which corresponds to the data from one channel, are read first before going over to the next 1 k block and the process is repeated.

This means that the address pointer has to be incremented by one at every clock pulse and after reading $N_{p}$ points, has to be incremented to the starting position of next lk block. The sequence of read address generated is shown in fig(3.8).

In order to achieve this sequence of addressing the address generator is built by cascading 10 bit and 3 bit counters. But in this case the 10 bit counter is clocked by the master clock. This will cause the address pointer to be incremented by one at every clock. When the output of this counter is clocks the 3 bit counter.

Hence, the address generator will now point to the starting location of the next 1 kB block. The read address generator circuit is shown in the overall circuit diagram. Refer to fig(3.9)

## Address Multiplexer:

With both S-RAMs involved in read and write operations, the two of them will have to be provided with both the read and write address sequences. So the outputs of the two address generators are time multiplexed, and the outputs of the multiplexer forms the address bus of the two memories. The control bits for the multiplexer are provided by the status registers. The address multiplexer is as indicated in the overall circuit diagram. Refer to fig (3.9).

READING SEQUENCE

FIG 3.8

## B. E. (E \& C) Final Year Project 1994-95 Bangalore University 3.3 CLOCK CONTROL CIRCUIT:

The clock control circuit is used for providing appropriate clock pulses to the various functional blocks. It is fed with a master clock from an external circuit. The clock signals provided are

- Memory address clock: clock for the memory address generators.
- Read and Write control signals: enabling signals for the S- RAMs and buffers.
- Clock Control for Analog circuitry: clocking pulses for the ADC, sampling clock for sample and hold circuits.

The method of generation of various signals is represented schematically in fig(3.10).

## Clock for Memory Address Generators:

The ADC being a pipe lined device has a delay of 4 clock pulses, between an analog signal being given at its input and the corresponding digitized data appearing at the ADC output. The digital data from the ADC is then written into SRAMs. So the address generators used for generating writing address should start only after this delay. A 3 bit synchronous self stopping counter is used for this purpose. The output of this counter is decoded and used to enable clock to the address generator.

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

At the time of power up or any ensuing initialization of the $\boldsymbol{B D R}$ this 3 bit counter is also cleared. It then accumulates 4 counts. On the 5th pulse this counter is stopped and the clock to the read and write address generator is enabled. The appropriate waveforms are indicated in fig(3.11).

## Read/Write Control Signals:

The two SRAMs and their associated buffers need control pulses, like output enable, write enable etc., for their operation. The read write controller in the clock control circuit generates these control pulses. The operation of each control pulse is discussed below briefly.

- BUF-OE: It is used to control the output of the buffer When BUF-OE is low, output of the buffer is enabled and with BUF-OE high, the output is tri-stated. *
- RAM-OE: This signal enables the output of the SRAMs. With RAM-OE low the data can be read out of the memory and if it is high the memory may be used for writing (if $\mathrm{WR}=1$ ). If RAM-OE is high output of memory will be tri-stated.
- RD/WR: This signal controls the state of the SRAMs, that is, it decides whether data can be written into the SRAM or read from it.

The read write controller logic circuit is indicated in the overall circuit diagram. The two D type flip-flops are so connected that their outputs are perpetually complements of each Dept. of $E \& C$ Engineering, R.V.C.E. Bangalore

## Bangalore University

other. Their outputs have been used to dictate the generation of the control pulses and thereby decide the status of the two memories (which is why the two of them together have termed as status registers). In fact, they give a clear indication of which memory is in read cycle and which is in the write cycle.

The RD/WR and RAM-OE signals should be pulses of duration less than the clock given to the counter to, prevent data being duplicated or overwritten in the memories. Different conditions resulting from different values of $\mathrm{WE}_{1}$ and $\mathrm{WE}_{2}$ are discussed below briefly:

- $\underline{W E}_{1}=0$ and $\mathbf{W E}_{2}=1$ : With $\mathrm{WE}_{1}=0 \mathrm{AND}_{1}$ is disabled and $\mathrm{AND}_{2}$ is enabled. The output of the $\mathrm{XOR}_{2}$ will be same as the pulse given to $\mathrm{AND}_{1}$ (since $\mathrm{WE}_{1}=0$ ). The output of the $\mathrm{XOR}_{1}$ will be continuously high $\left(\mathrm{WE}_{2}=1\right)$.
- $\underline{\mathbf{W E}}_{1}=1$ and $\mathbf{W E}_{2}=\mathbf{0}$ : With $\mathrm{WE}_{1}=1 \mathrm{AND}_{1}$ is enabled and $\mathrm{AND}_{2}$ is disabled. The output of $\mathrm{XOR}_{1}$ will be pulsating and output of $\mathrm{XOR}_{2}$ will be in high state continuously.

The $\mathrm{RD} / \mathrm{WR}_{1}$ and $\mathrm{RD} / \mathrm{WR}_{2}$ signal are also used to control the output of $\mathrm{SRAM}_{1}$ and $\mathrm{SRAM}_{2}$.

The logic discussed above has been programmed into EPM 7128LC84. The details of which are provided in the Appendix $D$. The final schematic of the $\boldsymbol{B D R}$ is also included in the following page.

# B. E. (E \& C) Final Year Project 1994-95 <br> Bangalore University 

## Analog clock Generators:

There are three signals that the digital control circuits have to provide the analog part of the circuit with, namely:

- ADC clocking
- Analog MUX selection
- Sampling clock for sample and hold circuits

The ADC clock frequency is same as the memory address clock frequency. It is directly provided by the clock controller.

The Analog MUX selection bits are generated by a 3 bit synchronous counter, which is clocked by ADC clock. Since this MUX has to switch between the selected number of channels, the counter has been made programmable. As earlier the PC, during the time of initializing the $\boldsymbol{B D R}$ card programs this counter also. The sampling clock is the signal given to the sample and hold circuits for putting them into the hold state. It is generated at the of $\left(1 / N_{c}\right)$ times the ADC clocking frequency, where $\mathrm{N}_{\mathrm{c}}$ is the number of channels input.

The circuit diagram of the analog clock control circuit is shown in fig(3.12).

B. E. (E \& C) Final Year Project 1994-95<br>Bangalore University

## MEMORY BANK:

The memory bank consists of two HY62C256/L ICs which are 32,768 word by 8-bit CMOS Static RAMs, of which only 8 k have been put to use. The HY62C256/L has a typical access time of 100 ns . The need for two such devices has been explicitly explained in previous chapters. Further details about HY62C256/L can be found in Appendix $D$.

## CHAPTER FOUR TESTING AND

## CONCLUSION

B. E. (E \& C) Final Year Project 1994-95

Bangalore University

### 4.1 TESTING OF DIGITAL CONTROL LOGIC

First the logic of the control system implemented using EPLD are tested. This is done by entering the required logic in to the graphic editor file of MAX + PLUS-2 (details of MAX +PLUS II are in Appendix $C$ and then simulating its functioning. Two levels of simulation are done:

Software Simulation: It is done before programming the logic into the EPLD. The desired inputs to the EPLD are entered into a simulator file as waveforms. The logic simulator on MAX $~+~ P L U S-2$ is then used to run a simulation of this file. The simulated outputs are observed in the simulator file. It is found to be in agreement with the desired results.

Hardware Simulation: The logic discussed earlier in chapter 3 is fused into a EPLD (EPM 7128) by the programmer of MAX + PLUS-2. For this the EPLD is placed in the MAX + PLUS-2 programming module. The programmed EPLD is now used to perform hardware simulation, i.e., the input signals (entered in simulator file) are generated from the PC and sent to the EPLD (placed in the adapter module). The EPLD outputs are monitored and this outputs are found to match with software output.
B. E. (E \& C) Final Year Project 1994-95

Bangalore University Testing Details:

The buffered data router being developed is a prototype board. It is therefore first implemented on general purpose PCB. This would help us make modifications, if necessary, in case of bugs found in the circuit, which would be a trouble-some process with a custom made PCB

Due to the non-availability of the required analog components at the right time, the Analog conditioning and digitizer circuit could not be implemented. So it was decided that the BDR and its associated control logic must be tested independent of these analog components

This can be achieved by a digital circuit that would simulate the output of the ADC . The output of such a digital circuit should preferably sequential and synchronous with the memory address clock. This will allow us to predict the output of the data router card effectively.

The digital circuit involved is a simple 3 bit counter. This 3 bit counter, called the test counter, is clocked at the same rate as the address generators (with necessary compensation for ADC pipe line delay).

Since the DSC itself is PC based, it is only apt that this project, the buffered data router is also PC based. The PC is used to initialize the Buffered Data Router (BDR), during which the number of channels and number of points the user specifies are loaded into the card. The interface between the PC and the BDR CARD is a 48 line I/O port (a 8255 based card, containing two 8255A chips). The card details can be obtained in Appendix $D$.

Dept. of E \& C Engineering, R.V.C.E. Bangalore

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

The 48 lines of the 8255 card have been split into two groups (1) 24 lines for input (2) 24 line for output. Out the 24 output lines 16 have been used: 11 for loading number of points, 4 for loading number of channels, one line for sending the enable pulse at the time of initialization

- Initializing the BDR and configuring the ports of I/O card is accomplished by a program written in $C$ language ${ }_{k}$ The program source code is given in the following page.

The program itself is user friendly and interactive. The tasks of initialization, acquisition and browsing of acquired data tave been made very simple with self explanatory menus.

Incidentally, a second 8 bit bus from the BDR sends the output data from the data router to the PC via the input port of the $8255 \mathrm{I} / \mathrm{O}$ card.

With write address being incremented by 1024 at every clock pulse (while the test counter is incremented by 1), a different number is written into each 1 kB block of the 8 kB memory. The numbers stored adjacent memory block will therefore differ by one. The data stored in memories are read out sequentially. Thereby reading all the number stored in a 1 k block before going over to the next ( 1 k block). The output sequence can now predicted. Each number is number will be repeated $\mathrm{N}_{\mathrm{p}}$ number of times. The block diagram of the test circuitry is shown in fig(4.1).

The PC clock and clock given BDR being different will not be synchronous. So the data output from BDR, may not be synchronized with the inport instruction executed by the

```

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

PC. This leads to the same data being read twice or it being completely lost: To overcome this problem, the synchronization circuit is used period. The output enable signal of the two SRAMs has been used to generate a Data Ready Signal (DRS) as shown in fig(4.2). This would inform the PC when fresh data has been put on the data bus. Care has also been to taken to prevent acquisition of data during the very first write cycle when the content of the one of the memory chips is invalid. The program will polling for this data ready signal and acquires a data point, at every DRS. This forms the necessary hand shake signal between the BDR and the host CPU or the DSC.

This data is stored in the memory of the PC, which can be down loaded into a file, in ASCII format, if the user so wishes. This allows for storing away the acquired data in the hard disk for later use. Since the data is stored in ASCII format any text editor can be used to view the contents of the file.

The Buffered Data Router was tested extensively in the afore said method. The card performed according to the specifications.

## B. E. (E \& C) Final Year Project 1994-95 Bangalore University

## CONCLUSION

The Multi channel digitizer card combined with the Buffered Data Router is a versatile tool in the field of data acquisition systems. It has ability to be programmed through a IBM 80 x 86 PC , with the help of menu driven program.

The most important feature of the Buffered Data Router, is that it can effectively convert a single DSC into a multi-channel one, without affecting the speed of the DSC. It can assist in General Spectral Analysis apart from using it for studying CRRLs.

The Analog Multiplexer forms a bottleneck in the entire system, with its high settling time. This again can be remedied easily, because this circuit has also been implemented on a separate PCB.

A very high speed ADC has been included into the circuit, on a separate PCB. The speed of the ADC is sufficing for all practical purposes. But in the future, if the need be, the ADC can be replace with a faster one, on availability of such a device. It can also be function as a laboratory spectrum analyzer.

Other than that the system can perform as a multi-channel data acquisition system. A data ready signal incorporated into the system can be used for synchronizing the board with the next stage.

## B. E. (E \& C) Final Year Project 1994-95 Bangalore University

## GEETEE

The Gauribidanur Radio Telescope is of the ARRAY type operating at 34.5 MHz center frequency with a bandwidth of 2 MHz . It is essentially a meridian transit instrument. The telescope consists of 1,000 broad band dipoles arranged in the form of the letter " $\mathbf{T}$ ". The outputs of four dipoles along East West (EW) direction are combined in a Christmas tree fashion using open wire (balanced) transmission lines, and transformers to form a "basic array element."

Such basic array elements, numbering two hundred and fifty are arranged to form a 1.38 km long EW array along the East West direction. Similarly ninety basic array elements are arranged to form a 0.45 km long south array along the south direction from the center of the EW array. The signals from the basic array units are brought to the laboratory through open wire transmission lines. East West array has an effective collecting area of approximately $12,000 \mathrm{~m}^{2}$. while that of the North South array is approximately $7,000 \mathrm{~m}^{2}$.

The receiver permits observation of a 150 patch of sky (in the N -S direction) with 46 beams. The resolution is $26 \times 40 \mathrm{sec} \mathrm{ZA}$ (ZA is the zenith angle). The sensitivity is around 20 Jansky.

APPENDIX B

## B. E. (E \& C) Final Year Project 1994-95 <br> CARBGOLOR University RECOMBINATION LINES [CRRLS]

These lines involve highly excited states, presumably of carbon, during the transient recombination of a carbon ion with an electron. These lines(representing the highest excited states yet detected in interstellar gas) should be valuable indicators of conditions in the interstellar medium. Assuming carbon as the element involved, the presumed scenario is that a singly ionized carbon ion $\left(\mathrm{C}^{+}\right)$recombines briefly with an electron. The resulting neutral, but highly excited states accompanied by emission or absorption. The higher the excitation, the more numerous and closely spaced the lines become so that the energies of transition ( $\eta \omega$ ) and the resulting frequencies(v)are less with many falling below 100 MHz .

The twelve CRRLs are listed below;

| SI. no. | Orbital Quantum Number ${ }^{\prime} \mathbf{n}{ }^{\prime}$ | Frequency in MHz |
| :---: | :---: | :---: |
| $\mathbf{1}$ | $\mathbf{5 7 0}$ | $\mathbf{3 5 . 4 3 3 8 9 8 9 2}$ |

# B. E. (E \& C) Final Year Project 1994-95 

## MAX + PLUS AND EPLD

MAX+PLUS - the MAX programmable logic user system from Altera Corporation is a "fully integrated package for developing and implementing custom logic circuits with Altera's Multiple Array Matrix (MAX) family of high density Erasable Programmable Logic Devices (EPLDs)". The MAX+PLUS software offers different ways to enter the circuit design, compiles and fits the design to use MAX architecture in the most efficient way possible, and generates a file for programming the EPLD. One can also simulate the logic and timing characteristics of the design. The MAX + PLUS hardware consists of a software controlled Logic Programming Unit used for device programming.

Programmable logic devices (known by various names such as PAL, PLA, PLD, EPLD etc.) combine the logistical advantages of standard, fixed integrated circuits with the architectural flexibility of custom devices. They allow to electrically program standard, off the shelf logic elements to meet the specific needs of their applications. This eliminates various problems due to use of individual ICs in a circuit and reduces the overall cost and the time for the design.

The fundamental building block of an EPLD is the "macrocell". Each macrocell consists of three parts.
(1) The logic array that implements all combinatorial logic functions.
(2) The programmable register that provides D, T, JK or SR flip-flops.
(3) Programmable I/O that allows each I/O pin to be configured as input, output, or bi-directional operation

Dept. of E \& C Engineering, R.V.C.E. Bangalore

## B. E. (E \& C) Final Year Project 1994-95

## Bangalore University

The logic array consists of a programmable AND/fixed-OR PLA array. Inputs to the AND array come from the true and complement of the dedicated input and clock pins, and from the macrocell and I/O feedback paths. The connections between them are opened during the programming process

Programmable flip-flop are used to create a variety of logic functions that use a minimum of EPLD resources. If the flip flop is not required for macrocell logic, it may simply be bypassed. In general purpose EPLDs each flip flop may be clocked from a dedicated system clock, any input or I/O pin or any internal logic function. EPLD registers are positive edge triggered with data transitions that occur on the positive edge of the clock. In addition, gated clock and clock enable logic can be implemented but their delay time is larger.

The EPLD I/O control block contains a tri-state buffer controlled by a ,macrocell product term and drives the I/O pin. I/O pins may be configured as dedicated outputs, bidirectional outputs, or as additional dedicated inputs.

The EPLDs have been, built using the " CMOS EPROM" technology. The density of the chips range from hundreds to thousands of gates, offered in variety of packages with 20 to 100 pins.

EPLD families are divided into two architectural categories. The first one is the general purpose group which provide maximum flexibility for general purpose logic replacement. The EP series and EPM5000 series come under this group. The second group are the function

## B. E. (E \& C) Final Year Project 1994-95 Bangalore University

specific EPLDs specialized for performing specific system design tasks. The EPB and EPS series constitutes this group.

EPLDs are offered in a variety of packages including the dual in-line package ( DIP ), J-lead chip carrier (JLCC ) , Quad Flat Pack ( QFP ) , Pin Grip Array ( PGA ) etc. EPLDs which are re-programmable are provided with windows are made of ceramic whereas, for high volume production one-time programmable plastic versions are available.

As already explained, the MAX+PLUS software is used for programming the chips.

ECM Systems
Radar Systems
Data Acquisition

## GENERAL DESCRIPTION

The AD9300 is a monolithic high-speed video signal multiplexer useable in a wide variety of applications.
Its four channels of video input signals can be randomly switched at megahertz rates to the single output. In addition, multiple devices can be configured in either parallel or cascade arrangements to form switch matrices. This flexibility in using the AD9300 is possible because the output of the device is in a high-impedance state when the chip is not enabled; when the chip is enabled; the unit acts as a buffer with a high input impedance and low output impedance.
An advanced bipolar process provides fast, wideband switching capabilities while maintaining crosstalk rejection of 75 dB at 10 MHz . Full power bandwidth is a minimum 30 MHz . The device can be operated from $\pm 10 \mathrm{~V}$ to $\pm 15 \mathrm{~V}$ power supplies.
The AD9300KQ is packaged in a 16 -pin ceramic DIP and is designed to operate over the commercial temperature range of $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$. For military temperatures of $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$, order part number AD9300TQ, which is also a 16 -pin ceramic DIP. In addition to DIP packages, the AD9300 is also available in a' 20 -pin LCC as the model AD9300TE, which operates over a temperature range of $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$.

## NOTES

'Permanent damage may occur if any one absolute maximum rating is exceeded. Functional operation is not implied, and device reliability may be impaired by exposure to higher-than-recommended voltages for extended periods of time.
${ }^{2}$ Military Subgroups apply to military-qualified devices only.
${ }^{3}$ Measured at extremes of temperature range.
${ }^{4}$ Measured as slope of $\mathrm{V}_{\mathrm{H}}{ }^{-1}$ versus $\mathrm{V}_{\mathrm{IN}}$ with $\mathrm{V}_{\mathrm{IN}}$ +IV.
${ }^{5}$ Measured as worst deviation from end-point fit with $V_{1 N}$.. $\pm 1 V$
${ }^{6}$ Full Power Bandwith' (FPBW) based on Slew Rate (SR). FPBW $=\mathrm{SR} / 2 \pi \mathrm{~V}_{\mathrm{PF} \text {.AK }}$
${ }^{7}$ Measured between $20 \%$ and $80 \%$ transition points of +1 V output
${ }^{8}$ T-Step - $\operatorname{Sin}^{2} \mathrm{X}$ Step, when Step between 0V and +700 mV points has $10 \%-t 0-90 \%$ risetime $=125 \mathrm{~ns}$.
${ }^{9}$ Measured with a pulse input having slew rate $>250 \mathrm{~V} / \mu \mathrm{s}$.
${ }^{10}$ Measured at output between 0.28 Vdc and 1.0 Vdc with $\mathrm{V}_{\mathrm{IN}}=284 \mathrm{mV}$ p-p at 3.58 MHz and 4.43 MHz .
${ }^{11}$ This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and $10 \mathrm{MHz} 2 \mathrm{~V} . \mathrm{p}-\mathrm{p}$ signal applied to remaining three channels. If selected channel is grounded through 750, value is approximately 6 dB higher.
${ }^{12}$ This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10 MHz 2 V p-p signal applied to one other channel. If selected channel is grounded through $75 \Omega$, value is approximately 6 dB higher.
${ }^{14}$ Consult system timing diagram.
${ }^{14}$ Measured from address change to $90 \%$ point of -2 V to +2 V output LOW-to-HIGH transition
"Measured from address change to $10 \%$ point of +2 V to -2 V output HIGH-to-LOW transition.
${ }^{10}$ Measured from $50 \%$ transition point of ENABLE input to $90 \%$ transition of 0 V to -2 V outpur.
${ }^{1 \%}$ Measured from $50 \%$ transition point of ENABLE input to $10 \%$ transition of +2 V to 0 V output.
${ }^{18}$ Measured while switching between two grounded channels.
${ }^{14}$ Maximum power dissipation is a package-dependent parameter related to the following typical thermal impedances:

Specifications subject to change without notice.

## EXPLANATION OF TEST LEVELS

Test Level I - $100 \%$ production tested.
Test Level II - $100 \%$ production tested at $+25^{\circ} \mathrm{C}$, and sample tested at specified temperatures.
Test Level III - Sample tested only.
Test Level IV - Parameter is guaranteed by design and characterization testing.
Test Level V - Parameter is a typical value only.
Test Level VI - All devices are $100 \%$ production tested at $+25^{\circ} \mathrm{C} .100 \%$ production tested at temperature extremes for military temperature devices; sample tested at temperature extremes for commercial/industrial devices.

## FUNCTIONAL DESCRIPTION

$\mathrm{IN}_{1}-\mathrm{IN}_{4} \quad$ Four analog input channels.
GROUND Analog input shielding grounds, not internally connected. Connect each to external low-impedance ground as close to device as possible.
$A_{0} \quad$ One of two TTL decode control lines required for channel selection. See Logic Truth Table.
$A_{1} \quad$ One of two TTL decode control lines required for channel selection. See Logic Truth Table.
ENABLE TTL-compatible chip enable. In enabled mode (logic HIGH), output signal tracks selected input channel; in disabled mode (logic LOW), output is high

| LOGIC TRUTH TABLE |  |  |  |
| :---: | :---: | :---: | :--- |
| ENABLE | $A_{1}$ | $A_{0}$ | OUTPUT |
| 0 | X | X | High Z |
| 1 | 0 | 0 | IN |
| 1 | 0 | 1 | $\mathrm{IN}_{2}$ |
| 1 | 1 | 0 | $\mathrm{IN}_{3}$ |
| 1 | 1 | 1 | $\mathrm{IN}_{4}$ |

- Vs $\quad$ Negative supply voltage; nominally -10 V dc to -15 V dc.
$+V_{S} \quad$ Positive supply voltage; nominally +10 V dc to +15 V dc .
OUTPUT Analog output. Tracks selected input channel when enabled.
BYPASS Bypass terminal for internal bias line; must be decoupled externally to ground through $0.1 \mu \mathrm{~F}$ capacitor.
GROUND Analog signal and power supply ground return.

## THEORY OF OPERATION

As shown on the drawing, this diagram is based on the pinouts of the DIP packaging of the models AD9300KQ and AD9300TQ. The AD9300TE is packaged in a 20 -pin leadless chip carrier (LCC), but the extra pins are used for ground connections; the theory of operation remains the same.

The AD9300 Video Multiplexer allows the user to connect any one of four analog input channels $\left(\mathrm{IN}_{1}-\mathrm{IN}_{4}\right)$ to the output of the device, and to switch between channels at megahertz rates.
The input channel which is connected to the output is determined by a 2-bit TTL digital code applied to $\mathrm{A}_{0}$ and $\mathrm{A}_{1}$. The selected input will not appear at the output unless a digital "l" is also applied to the ENABLE inpur pin; unless the output is enabled. it is a high impedance. Necessary combinations to accomplish channel selection are shown in the Logic Truth Table.
Bipolar construction used in the AD9300 insures that the input impedance of the device remains high, and will not vary with power supply voltages: This characteristic makes the AD9300, in effect, a switchable-input buffer. An on-board bias network makes the performance of the AD9300 independent of applied supply voltages, which can have any nominal value from $\pm 10 \mathrm{~V}$ de to $\pm 15 \mathrm{~V}^{\mathrm{d}} \mathrm{d}$.

Although the primary application for the AD9300 is the routing of video signats, the harmonic and dynamic attributes of the device make it appropriate for other applications. The AD9300 has exceptional performance when switching video signals, but can also be used for switching other analog signals requiring greater dynamic range and/or precision than those in video.

As shown in Figure 1, Input and Output Equivalent Circuits, each analog input is connected to the base of a bipolar transistor. If Channel 1 is selected, a current switch is closed and routes current through the input transistor for Channel 1.
If Channel 2 is then selected by the digital inputs, the current switch for Channel 1 is opened and the current switch for Channel 2 is closed. This causes current to be routed away from the Channel 1 transistor and into the Channel 2 input transistor. Whenever a channel's input device is carrying current, the analog input applied to that channel is passed to the output stage.
The operation of the output stage is similar to that of the input stages. Whenever the output stage is enabled with a HIGH digital "l" signal at the ENABLE pin, the output transistor will carry current and pass the selected analog input.

Figure 1. Input and Output Equivalent Circuits

When the output stage is disabled (by virtue of the ENABLE pin being driven L()W with a digital " 0 "), the output current switch is opened. This routes the current to other circuits within the AD9300 which keep the output transistor biased "off". These circuits require approximately $1 \mu A$ of bias current from the load connected to the ourput of the multiplexer. In the absence of a terminating load and the resulting de bias, the output of the AD9300 "floats" at -2.5 V .
In summary, when the $A D 9300$ is enabled by the ENABLE pin being driven HIGH with a digital " 1 ", the selected analog input channel acts as a buffer for the input; and the output of the multiplexer is a low impedance. When the AD9300 is disabled with a digital " 0 " LOW signal, the selected channel acts as an open switch for the input; and the output of the unit becomes a high impedance. This characteristic allows the user to wire-or several AD9300 Analog Multiplexers together to form switch matrices.

## AD9300 APPLICATIONS

To ensure optimum performance from circuits using the AD9300, it is important to follow a few basic rules which apply to all high-speed devices.
A large, low-impedance ground plane under the ADO9300 is critical. Gencrally, GROUND and GROUND RETURN connections should be connected solidly to this plane. GROLND pin connections are signal isolation grounds which are not connected internally; they can be left unconnected, but there may be some degradation in crosstalk rejection. GROUND RETURN, on the other hand, serves as the internal ground reference for the AD9300 and should be connected to the ground plane without exception.
It is recommended that the AD9300 be soldered directly into circuit boards, rather than using socket assemblies. If sockets must be used, individual pin sockets are the preferred choice, rather than a socket assembly. A second requirement for proper high-speed design involves decoupling the power supply and internal bias supply lines from ground to improve noise immunity. Chip eapacitors are recommended for connecting $0.1 \mu \mathrm{~F}$ and $0.01 \mu \mathrm{~F}$ capacitors between ground and the $\pm \mathrm{V}_{S}$ supplies (Pins 9 and 14), and the BYPASS connection (Pin 15).

The output stage of the unit is capable of driving a $2 \mathrm{k} \Omega \Omega_{1} 10 \mathrm{pF}$ load. Larger capacative loads may limit full power bandwidth and increase toff (the interval between the $50 \%$ point of the ENABLE high-to-low transition and the instant the output becomes a high impedance.)
For applications such as driving cables (See Figure 2), output buffers are recommended.

Figure 2. $4 \times 1$ AD9300 Multiplexer with Buffered Output Driving $75 \Omega$ Coaxial Cable

Imaging/FLIR Systems
Peak Detectors
Radar/EW/ECM
Spectrum Analysis
CCD ATE

## GENERAL DESCRIPTION

The AD9100 is a monolithic track-and-hold amplifier which sets a new standard for high speed and high dynamic range applications. It is fabricated in a mature high speed complementary bipolar process. In addition to innovative design topologies, a custom package is utilized to minimize parasitics and optimize dynamic performance.
Acquisition time (hold to track) is 13 ns to $0.1 \%$ accuracy, and 16 ns to $0.01 \%$. The AD9100 boasts superlative hold-mode frequency domain performance; when sampling at 30 MSPS hold mode distortion is less than -83 dBfs for analog frequencies up to 12 MHz ; and -74 dBfs at 20 MHz . The AD9 100 can also drive capacitive loads up to 100 pF with little degradation in acquisition time; it is therefore well suited to drive 8 - and 10 -bit flash converters at clock speeds to 50 MSPS. With a spectral noise density of $3.3 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ and feedthrough rejection of 83 dB at 20 MHz , the AD9100 is well suited to enhance the dynamic range of many 8 - to 16 -bit systems.

## *Patent pending.

AD9100 BLOCK DIAGRAM

The AD9100 is "user friendly" and easy to apply: (1) it requires $+5 \mathrm{~V} /-5.2 \mathrm{~V}$ power supplies; (2) the hold capacitor and switch power supply decoupling capacitors are built into the DIP package; (3) the encode clock is differential ECL to minimize clock jitter; (4) the input resistance is typically $800 \mathrm{k} \Omega$; (5) the analog input is internally clamped to prevent damage from voltage transients.
The AD9100 is available in a 20 -lead side-brazed "skinny DIP" package. Commercial, industrial, and military temperature grade parts are available. Consult the factory for information about the availability of surface mount packages and 883 -qualified devices.

## PRODUCT HIGHLIGHTS

1. Hold Mode Distortion is guaranteed.
2. Monolithic construction.
3. Analog input is internally clamped to protect against overvoltage transients and ensure fast recovery.
4. Output is short circuit protected.
5. Drives capacitive loads to 100 pF .
6. Differential ECL clock inputs.

## AD9100 PINOUTS

## AD9100

Acquisition Time is the amount of time it takes the AD9100 to reacquire the analog input when switching from hold to track mode. The interval starts at the $50 \%$ clock transition point and ends when the input signal is reacquired to within a specified error band at the hold capacitor.
Analog Delay is the time required for an analog input signal to propagate from the device input to output.
Aperture Delay tells when the input signal is actually sampled. It is the time difference between the analog propagation delay of the front-end buffer and the control switch delay time. (The time from the hold command transition to when the switch is opened.) For the AD9100, this is a positive value which means that the switch delay is longer than the analog delay.

Aperture Jitter is the random variation in the aperture delay This is measured in ps-rms and results in phase noise on the held signal.
Droop Rate is the change in output voltage as a function of time ( $\mathrm{dV} / \mathrm{dt}$ ). It is measured at the AD9100 output with the device in hold mode and the input held at a specified dc value; the measurement starts immediately after the T/H switches from track to hold.

Feedthrough Rejection is the ratio of the input signal to the output signal when in hold mode. This is a measure of how well the switch isolates the input signal from feeding through to the output.
Hold to Track Switch Delay is the time delay from the track command to the point when the output starts to change and acquire a new signal.
Pedestal Offset is the offset voltage step measured immediately after the AD9100 is switched from track to hold with the input held at zero volts. It manifests itself as an added offset during the hold time.

Track to Hold Settling Time is the time necessary for the track to hold switching transient to settle to within 1 mV of its final value.

Track to Hold Switching Transient is the maximum peak switch induced transient voltage which appears at the AD9100 output when it is switched from track to hold.

## THEORY OF OPERATION

The AD9100 utilizes a new track and hold architecture. Previous commercially available high speed track and holds used a front end open loop input buffer, followed by a diode bridge, hold capacitor, and output buffer (closed or open loop) with a FET device connected to the hold capacitor. This architecture required mixed device technology and, usually, hybrid construction. The sampling rate of these hybrids has been limited to 20 MSPS for 12 -bit accuracy. Distortion generated in the front-end amplifier/bridge limited the dynamic range performance to the "mid- 70 dBfs " for analog input signals of less than 10 MHz . Broadband and switch-generated noise limited the SNR of previous track and holds to about 70 dB .
The AD9100 is a monolithic device using a high frequency complementary bipolar process to achieve new levels of high speed precision. Its patent pending architecture breaks from the traditional architecture described above. (See the block diagram on the first page.) The switching type bridge has been integrated into the first stage closed loop input amplifier. This innovation provides error (distortion) correction for both the switch and amplifier, while still achieving slew rates representative of an open-loop design. In addition, acquisition slew current for the hold capacitor is higher than standard diode bridge and switch configurations, removing a main contributor to the limits of maximum sampling rate and input frequency.
Switching circuits in the device use current steering (versus voltage switching) to provide improved isolation between the switch and analog sections. This results in low aperture time sensitivity. to the analog input signal, and reduced power supply and analog switching noise. Track to hold peak switching transient is typically only 6 mV and settles to less than 1 mV in 7 ns . In addition, pedestal sensitivity to analog input voltage is very low $(0.6 \mathrm{mV} / \mathrm{V})$ and being first order linear does not significantly affect distortion.
The closed-loop output buffer includes zero voltage bias current cancellation, which results in high-temperature droop rates equivalent to those found in FET type inputs. The buffer also provides first order quasistatic bias correction resulting in an extremely high input resistance and very low droop sensitivity vs. input voltage level (typically less than $1.5 \mathrm{mV} / \mathrm{V}-\mu \mathrm{s}$.) This closed-loop architecure inherently provides high speed loop correction and results in low distortion under heavy loads.
The extremely fast time constant linearity ( 7 ns to $0.01 \%$ for a 2 V step) ensures that the output buffer does not limit the AD9100 sampling rate or analog input frequency. (The acquisition and settling time are primarily limited only by the input amplifier and switch.) The output is transparent to the overall AD9100 hold mode distortion levels for loads as low as $250 \Omega$.
Full-scale track and acquisition slew rates achieved by the AD9100 are 800 and $1000 \mathrm{~V} / \mu \mathrm{s}$, respectively. When combined with excellent phase margin (typically $5 \%$ overshoot), wide bandwidth, and dc gain accuracy, acquisition time to $0.01 \%$ is only 16 ns. Though not tested, settling to 14 -bit accuracy .88 dB distortion (a 2.3 MHz ) can be inferred to be 20 ns

## Acquisition Time

Acquisition time is the amount of time it takes the AD9100 to reacquire the analog input when switching from hold to track mode. The interval starts at the $50 \%$ clock transition point and ends when the input signal is reacquired to within a specified error band at the hold capacitor.

The hold to track switch delay ( $t_{D H} t$ ) can not be subtracted from this acquisition time because it is a charging time delay that occurs when moving from bold to track; this is typically 4 to 6 ns and is the longest delay. Therefore, the track time required for the AD9100 is the acquisition time, which includes $t_{\text {DHT }}$. Note that the acquisition time is defined as the settled voltage at the hold capacitor and does not include the delay and settling time of the output buffer. The example below illustrates why the output buffer amplifier does not contribute to the overall AD 9100 acquisition time.

Figure 1. Acquisition Time Diagram
The exaggerated illustration in Figure 1 shows that $V_{C H}$ has setthed to within $\mathrm{x} \%$ of its final value; but $\mathrm{V}_{\mathrm{OUT}}$ (due to slew rate limitations, finite $B W$, power supply ringing, etc.) has not setthed during the track time. However, since the output buffer always "tracks" the front end circuitry, it "catches up" during the hold time and directly superimposes itself (less about 600 ps of analog delay) to $\mathrm{V}_{\mathrm{CH}}$. Since the small-signal settling time of the output buffer is about 1.8 ns to $\pm 1 \mathrm{mV}$ and is significantly less than the specified hold time, acquisition time should be referenced to the hold capacitor.
Note that most of the hold settling time and output acquisition time are due to the input buffer and the switch network. For output acquisition time, the output buffer contributes only about 5 ns of the total; in hold mode, it contributes only 1.8 ns (as stated above).
A stricter definition of acquisition time would total the acquisition and hold times to a defined accuracy. To obtain $12 \mathrm{bit}+$ distortion levels and 30 MSPS operation, the recommended track and hold times are 20 ns and 13.5 ns , respectively. To drive an 8 -bit flash converter with a 2 V p-p full-scale input, hold time to 1 LSB accuracy will be limited primarily by the encoder, rather than by the AD9100. This makes it possible to reduce track time to approximately 13 ns , with hold time chosen to optimize the encoder's performance.

## AD9100

## Hold vs. Track Mode Distortion

In many traditional high speed, open loop track-and-holds, track mode distortion is often much better than hold mode distortion.
Track mode distortion does not include nonlinearities due to the switch network, and does not correlate to the relevant hold mode distortion. But since hold mode distortion has traditionally been omitted from manufacturer's specification tables, users have had to discover for themselves the effective overall hold mode distortion of the combined T/H and encoder.

The architecture of the AD9100 minimizes hold mode distortion over its specified frequency range. As an example, in track mode the worst harmonic generated for a 20 MHz input tone is typically -65 dBfs . In hold mode, under the same conditions and sampling at 30 MSPS , the worst harmonic generated is -74 dBfs . The reason is the output buffer in hold mode has only de distortion relevancy. With its inherent linearity ( 7 ns settling to $0.01 \%$ ), the output buffer has essentially settled to its dc distortion level even for track. plus hold times as short as 30 ns . For a traditional open-loop output buffer, the ac (track mode) and dc (hold mode) distortion levels are often the same.

## Droop Rate

Droop rate does not necessarily affect a track and hold's distortion characteristics. If the droop rate is constant versus the input voltage for a given hold time, it manifests itself as a dc offset to the encoder. For the AD9100, the droop rate is typically $\pm 1 \mathrm{mV} / \mu \mathrm{s}$. If a signal is held for $1 \mu \mathrm{~s}$, a subsequent encoder would see a 1 mV offset voltage. If there is no droop sensitivity to the held voltage value, the 1 mV offset would be constant and "ride" on the input signal and introduce no hold-mode nonlinearities.
In instances in which droop rate varies proportionately to the magnitude of the held voltage signal level, a gain error only is introduced to the A/D encoder. The AD9100 has a droop sensitivity to the input level of $1.5 \mathrm{mV} / \mathrm{V}-\mu \mathrm{sec}$. For a 2 V p-p input signal, this translates to a $0.15 \% / \mu \mathrm{s}$ gain error and does not cause additional distortion errors.

For the AD9100, droop sensitivity to input level is insignificant. However, hold times longer than about $2 \mu \mathrm{~s}$ can cause distortion due to the $\mathrm{R} \times \mathrm{C}_{\mathrm{H}}$ time constant at the hold capacitor. In addition, hold mode noise will increase linearly vs. hold time and thus degrade SNR performance.

## Layout Considerations

For best performance results, good high speed design techniques must be applied. The component (top) side ground plane should be as large as possible; two-ounce copper cladding is preferable. All runs should be as short as possible, and decoupling capacitors must be used.
Figure 2 is the schematic of a recommended AD9100 evaluation board. (Contact factory concerning availability of assembled boards.) All $0.01 \mu \mathrm{~F}$ decoupling capacitors should be low inductance surface mount devices ( $\mathrm{P} / \mathrm{N} 05085 \mathrm{C} 103 \mathrm{MT} 050$ from AVX) and connected on the component side within 30 mils of the designated pins; with the other sides soldered directly to the top ground plane

The $10 \mu \mathrm{~F}$ low frequency power supply tantalum decoupling capacitors should be located within 1.5 inches of the AD9100. The common $0.01 \mu \mathrm{~F}$ supply capacitors can be wired together. The common power supply bus (connected to the $10 \mu \mathrm{~F}$ capacitor and power supply source) can be routed to the underside of the board to the daisy chain wired $0.01 \mu \mathrm{~F}$ supply capacitors.
For remote input and/or output drive applications, controlled impedances are required to minimize line reflections which will reduce signal fidelity. When capacitive and/or high impedance levels are present, the load and/or source should be physically located within approximately one inch of the AD 9100 . Note that a series resistance, $R_{S}$, is required if the load is greater than 6 pF . (The Recommended $\mathrm{R}_{\mathrm{s}}$ vs. CL chart in the "Typical Performance Section" shows values of $R_{S}$ for various capacitive loads which result in no more than a $20 \%$ increase in settling time for loads up to 80 pF .) As much of the ground plane as possible should be removed from around the $V_{\text {IN }}$ and $V_{\text {OUT }}$ pins to minimize coupling onto the analog signal path.
While a single ground plane is recommended, the analog signal and differential ECL clock ground currents follow a narrow path directly under their common voltage signal line. To reduce reflections, especially when terminations are used for transmission line efficiency, the clock, $\mathrm{V}_{\text {IN }}$, and $\mathrm{V}_{\text {OUT }}$ signals and respective ground paths should not cross each other; if they do, unwanted coupling can result.
High current ground transients via the high frequency decoupling capacitors can also cause unwanted coupling to the $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {Out }}$ current loops. Therefore, these analog terminations should be kept as far as possible from the power supply decoupling capacitors to minimize feedthrough.

## Using Sockets

Pin sockets (P/N 6-330808-3 from AMP) should be used if the device can not be soldered directly to the PCB. High profile or wire wrap type sockets will dramatically reduce the dynamic performance of the device in addition to increasing the case-toambient thermal resistance.

## Driving the Encode Clock

The AD9100 requires a differential ECL clock command. Due to the high gain bandwidth of the AD9100 internal switch, the input clock should have a slew rate of at least $100 \mathrm{~V} / \mu \mathrm{s}$.
To obtain maximum signal to noise performance, especially at high analog input frequencies, a low jitter clock source is required. The AD9100 clock can be driven by an AD96685, an ultrahigh speed ECL comparator with very low jitter.

Clock/ $\overline{\text { Clock }}$ Input Stage

Figure 2. AD9100 Application Diagram

## Driving the Analog Input

Special care must be taken to ensure that the analog input signal is not compromised before it reaches the AD9100. To obtain maximum signal to noise performance, a very low phase noise analog source is required. In addition, input filtering and/or a low harmonic signal source is necessary to maximize the spurious free dynamic range. Any required filtering should be done close to the AD9100 and away from any digital lines.

## Overdriving the Analog Input

The AD9100 has input clamps that prevent hard saturation of the output buffer, thereby providing fast over-voltage recovery when the analog input transitions to the linear region ( $\pm 2 \mathrm{~V}$ ). The clamps are set internally at $\pm 2.3 \mathrm{~V}$ and cannot be altered
by the user. The output settles to $0.1 \%$ of its value 21 ns after the over-voltage condition is alleviated. When the analog input is outside the linear region, the analog output will be at either +2.2 V or -2.2 V .

## Matching the AD9100 to A/D Encoders

The AD9100's analog output level may have to be offset or amplified to match the full-scale range of a given $A / D$ converter. This can generally be accomplished by inserting an amplifier after the AD9100. For example, the AD671 is a 12 -bit 500 ns monolithic ADC encoder that requires a 0 to +5 V full-scale analog input. An AD84X series amplifier could be used to condition the AD9100 output to match the full-scale range of the AD671.

## FEATURES

Monolithic 10-Bit 18 MSPS A/D Converter Low Power Dissipation: 1.2 W
Signal-to-Noise Plus Distortion Ratio
$\mathrm{f}_{\mathrm{IN}}=1 \mathrm{MHz}: 56 \mathrm{~dB}$
$\mathrm{f}_{\mathrm{iN}}=8 \mathrm{MHz}: 53 \mathrm{~dB}$
Guaranteed No Missing Codes
On-Chip Track-and-Hold Amplifier
100 MHz Full Power Bandwidth
High Impedance Reference Input Out of Range Output
Twos Complement and Binary Output Data Available in Commercial and Military Temperature Ranges

## PRODUCT DESCRIPTION

The AD773 is a monolithic 10 -bit, 18 MSPS analog-to-digital converter incorporating an on-board, high performance track-and-hold amplifier (THA). The AD773 converts video bandwidth signals without the use of an external THA. The AD773 implements a multistage differential pipelined architecture with output error correction logic. The AD773 offers accurate performance and guarantees no missing codes over the full operating temperature range.
Output data is presented in binary and twos complement format. An out of range (OTR) signal indicates the analog input voltage is beyond the specified input range. OTR can be decoded with the $\mathrm{MSB} / \overline{\mathrm{MSB}}$ pins to signal an underflow or overflow condition. The high impedance reference input allows multiple AD773s to be driven in parallel from a single reference.
The combined dc precision and dynamic performance of the AD773 is useful in a variety of applications. Typical applications include:' video enhancement, HDTV, ghost cancellation, ultrasound imaging, radar and high speed data acquisition.
The AD773 was designed 'using Analog Devices' ABCMOS-1 prowess which utilizes high speed bipolar and 2-micron CMOS * transistors on a single chip. High speed, precision analog circuits are now combined with high density logic circuits. Laser trimmed thin film resistors are used to optimize accuracy and temperature stability.
The AD773 is packaged in a 28 -pin ceramic DIP and is available in commercial $\left(0^{\circ} \mathrm{C}\right.$ to $+70^{\circ} \mathrm{C}$ ) and military ( $55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ ) grades.

## FUNCTIONAL BLOCK DIAGRAM

## PRODUCT HIGHLIGHTS

1. On-board THA

The high impedance differential input THA eliminates the need for external buffering or sample and hold amplifiers. The THA offers the choice of differential or single-ended inputs. Input current is typically $5 \mu \mathrm{~A}$.
2. High Impedance Reference Input The high impedance reference input ( $200 \mathrm{k} \Omega$ ) allows direct connection with standard +2.5 V references, such as the AD680, AD580 and REF43.
3. Output Data Flexibility

Output data is available in bipolar offset and bipolar twos complement binary format.
4. Out of Range (OTR)

The OTR output bit indicates when the input signal is beyond the AD773's input range.

## CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

## EQUIVALENT REFERENCE INPUT CIRCUIT

The AD773 is designed to have a reference to analog input voltage ratio of $2.5: 1$. When the AD 773 is configured for singleended operation a 2.5 volt reference input establishes a full-scale analog input voltage of $1 \mathrm{Vp}-\mathrm{p}( \pm 500 \mathrm{mV}$ with respect to $\mathrm{V}_{\text {1NB }}$ ). Although the AD773 is specified and tested with $\mathrm{V}_{\text {REF }}$ equal to 2.5 V and $\mathrm{V}_{\mathrm{IN}}$ equal to $\pm 500 \mathrm{mV}$ the reference input voltage and analog input voltages can be changed. To optimize the AD773's performance the $2.5: 1$ ratio should be maintained. The simplified model of the AD773's reference input circuit is shown in Figure 22.

Figure 22. Typical Reference Input Circuit
The 2.5 V external reference is applied across resistor R1 producing a current which in turn generates a voltage $\mathrm{V}_{\mathrm{blas}}$ : Multiple reference currents are generated from $\mathrm{V}_{\text {BIas }}$ and are used throughout the converter. R3 is used to cancel errors induced by the input bias current of the REFGND buffer. Figure 23 shows the SNR performance as the reference voltage is varied from its nominal value of 2.5 V . The input full-scale voltage is defined by the following equation,

$$
\text { Input Full-Scale Voltage }=\frac{\text { Reference Voltage }}{2.5}
$$

The power dissipation is modulated by variations in the reference voltage. Figure 24 shows the variation in power dissipation versus reference voltage.

Figure 23. $S / N+D$ vs. Reference Input Voltage. $f_{\text {lin }} 18 \mathrm{MSPS}, \mathrm{fin}_{\mathrm{IN}} 1 \mathrm{MHz}$

Figure 24. Power Dissipation vs. Reference Input Voltage

## TRANSIENT RESPONSE

The fast settling input THA accurately converts full-scale input voltage swings in under one clock cycle. The THA's high impedance, fast slewing performance is critical in multiplexed or dc stepped (charge coupled devices, infrared detectors) systems. Figure 25 show the AD773's settling performance with an input signal stepped from -500 mV to 0 V . As can be seen, the output code settles to its final value in under one clock cycle.

Figure 25. Typical AD773 Settling Time

## OUTPUT DATA FORMAT

The Al)773 prowite hoth MSB and MSB outputs, delivering frative trae othet bindre and wos complement output data. Table II show the AI) 773 sutput data format.

Table II. Output Data Format

## OUT OF RANGE

An out-ot-range condomen exwls when the analog input voltage is hevond the input range $500 \mathrm{~m} / \mathrm{l}$ of the converter. Note the AD773 ha $1+$ chock crele latenc rating.] OTR (Pin 20) is vet low when the analog mput voltage is within the analog input range. ()TR is set HIGH and will reman HIGH when the analog input voltage exceeds the mput range by $1 / 2 \mathrm{LSB}$ trom the center of the full-scale output codes. OTR will remain HIGH until the analog input is within the input range. By logical A. Ding OTR wath the MSB and its complement, overrange high or underrange low condmons can be detected. Table III is a truth table for the ower under range cirent in Figure 26. Sistems requirme programmahle gam wnditioning prior to the A1)T73 can immediatcle detect an out of range conditon. thus chminatang gatis velectom fleratom

| 0 | 0 | In Range |
| 0 | 1 | In Range |
| 1 | 0 | Underrange |
| 1 | 1 | Overrange |

## GROUNDING AND LAYOUT RULES

As is the case for any high performance device, proper grounding and lavout techniques are essential in achieving optimal performance. (Note-Figures 28-32 are not to scale.) The analog and digital grounds on the AD773 have been separated to optimize the management of return currents in a system. It is recommended that a + -layer printed circuit board (PCB) which employs ground planes and power planes be used with the AD773. The use of ground and power planes offers distinct advantages:

1. The minimization of the loop area encompassed by a signal and its return path.
2. The minimization of the impedance associated with ground and power paths.
3. The inherent distributed capacitor formed by the power plane, PCB insulation, and ground plane.
These characteristics result in both a reduction of electromagnetic interference (EMI and an overall improvement in performance.
It is important to design a layout which prevents noise from coupling onto the input signal. The wide input bandwidth of the AD773 permits noise outside the desired Nyquist bandwidth to be digitized along with the desired signal. This can result in a higher overall level of spurious noise in the digitized spectrum. Digital signals should not be run in parallel with the input signal traces and should be routed away from the input circuitry. It is also suggested that the traces associated with $V_{\text {INA }}$ and $V_{\text {inh }}$ be the same length.

Separate analog and digital grounds should be joined together directly under the AD773 see Figure 30 ). A solid ground plane under the AD773 is also acceptable if care is taken in the management of the power and ground return currents. A general "rule-of-thumb" for mixed signal lavouts dictate that the return currents from digital circuitry should not pass through critical analog circuitr:

## POWER SUPPLY DECOUPLING

The analog and digital supplies of the AD773 have been separated to prevent the typically large transients associated with digital circuitry from coupling into the analog supplies ( $A V_{10 D}$, $A V_{S S}$ ). Each analog power supply pin should be decoupled with a $0.1 \mu \mathrm{~F}$ capacitor located as close to the pin as possible. Additionally, $0.22 \mu \mathrm{~F}$ capacitors for the $\mathrm{DRV}_{\mathrm{DD}}$ and $D V_{\mathrm{I}) \mathrm{D}}$ supplies are required to adequately suppress high frequency noise. For optimal performance, surface-mount capacitors are recommended. The inductance associated with the leads of throughhole ceramic capacitors typically render them ineffective at higher frequencies. A complete system will also incorporate tantalum capacitors in the $10-100 \cdot \mu \mathrm{~F}$ range to decouple low frequency noise and ferrite beads to limit high frequency noise.
The digital supplies have also been separated into $D R V_{\text {DD }}$ and $D V_{\text {DI }}$. The $D R V_{\text {In }}$ pins provide power for the digital output drivers of the AD773 and are likely to contain high energy transients. Pin 22 should be decoupled directly to Pin 21 (DRGND) and Pin 7 should be decoupled directly to Pin 8 (DRGND) to minimize the length of the return path for these transients. A single $+5 V$ supply is all that is required for $D R V_{1,1}$, and $D V_{1,1}$, but decoupling $\mathrm{DV}_{(1 n)}$, with an KC filter network is suggested (see Figure 27)

## 54F/74F240•54F/74F241•54F/74F244 Octal Buffers/Line Drivers with TRI-STATE® Outputs

General Description
The 'F240, 'F241 and 'Fic44 are octal butters and line driv-位 eceivers which provide improved PC and board density.

Features

- TRI.STATE outputs dive bus lines or buffer memory dress registers
- Outputs sink 64 mA ( 48 mA mil)
- 12 mA source current
- Input clamp diodes limit high-sped termination effects
- Guaranteed 4000 V minimum ESD protection

Ordering Code: See Section 5
Connection Diagrams

## DESCRIPTION

The HY62C256/L is a high speed low power, 32768-word by 8 -bit CMOS static RAM fabricated using HYUNDAI's high performance twin tub CMOS process. This high reliability process coupled with innovative circuit design techniques, yields access times of 100 ns maximum.

The HY62C256L has a data retention mode that guarantees data will remain valid at a minimum power supply voltages of 2.0 volts. Using twin tub CMOS technology, supply voltages from 2.0 to 5.5 volis have little effect on supply current in data retention mode. Reading the supply voltage to minimize current drain is unnecessary with the HY62C256/L family.

## FEATURES

- High speed - 100/120/150 ns (Max)
- Low Power dissipation. -200 mW (Typ.) Operating $-25 \mu \mathrm{~W}$ (Typ.) Standby (HY62C256L)
- Data retention supply voltage: $2.0-5.5 \mathrm{~V}$
- Four transistor 2-Load Register memory cell
- Fully static operation
-No clock or refresh required
- All inputs and outputs directly TTL compatible
- Tri-state outputs
- High reliability 28-pin 600 mil P-DIP

[^2]
## TIMING DLAGRAMS

READ CYCLE $1^{11)}$

READ CYCLE ${ }^{(1,2.4)}$

READ CYCLE $3^{14.3 .4}$

## NOTES:

1. $\overline{W E}$ is High for Read Cycle.
2. Device is contunuously selected. $\bar{\Gamma}=\mathbf{V}_{11}$
3. Address talid prior to or coinzeexa with $\overline{\mathrm{CS}}$ ransition lon.
t. $\overline{O E}=V_{11}$
4. Transition is measured $\pm 500 \mathrm{ma}$ \%emseady state. This parameter is sampled and no: $100 \%$ tested.

## WRITE CYCLE 1

WRITE CYCLE $2^{(5)}$

## NOTES:

1. A write occurs during the overlap ( $f_{u p}$ ) of a low $\overline{\mathrm{CS}}$ and low $\overline{W E}$.
2. In $x$ is measured from the earlier of $\overline{\mathrm{CS}}$ or $\overline{\text { WE }}$ going high to the end of write cycle.
3. During this period. 1/O pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
4. If the $\overline{\mathrm{CS}}$ low transition occurs simultaneously with the $\overline{W E}$ low transitions or after the $\bar{W}$ transition, outputs remain in a high impedance state.
5. $\overline{O E}$ is continuously low ( $\overline{O E}=V_{11}$ ).
6. $D_{\text {ex }}$ is the same phase of write data of this write cycle.
7. $D_{1} y$ is the read data of next address.
8. If $\overline{\mathrm{CS}}$ is low during this period, I 0 pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
9. Transition is measured $\pm 500 \mathrm{mV}$ from steady state. This parameter is sampled and not $100 \%$ tested.

LOW VCC DATA RETENTION CHARACTERISTICS
